Web-Based Data Access and Visualization

Scott Christensen | Civil Engineering, Dr. Norm Jones | Brigham Young University

**Goal**
- Provide an easy-to-use interface for accessing, exploring, processing, and visualizing data collected from the iUTAH project.

**Research Methodology**
- Stream data into an online database where it can be properly documented with meta-data and linked to a central hub that makes the data easily searchable.
- Provide a system where data can be fed into server-based models and automated workflows.
- Link data to a custom web interface where it can be visualized through maps, charts, and graphs and downloaded for additional analysis, modeling, and research.

**Results**
- A web application has been developed to automate the creation of groundwater maps (www.ci-water.byu.edu/groundwatermapping).
- A system using all open source tools is being developed to replace proprietary software.
- A framework for online modeling and visualization will allow future researchers to access data and cloud computing more readily.
